I. GATHER Statement

This study complies with the Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER) recommendations. We have documented the steps involved in our analytical procedures and detailed the data sources used in compliance with GATHER. For additional GATHER reporting, please refer to Methods Appendix Table 1 below.

Methods Appendix Table 1: GATHER Checklist

| # | GATHER checklist item | Description of compliance | Reference |
|---|---|--|---|
| Objectives and funding | | | |
| 1 | Define the indicators, populations, and time periods for which estimates were made. | Narrative provided in paper and methods appendix describing indicators, definitions, and populations | Main text (Methods—Overview, Geographic units and time periods) and methods appendix |
| 2 | List the funding sources for the work. | Funding sources listed in paper | Summary (Funding) |
| Data Inputs | | | |
| <i>For all data inputs from multiple sources that are synthesized as part of the study:</i> | | | |
| 3 | Describe how the data were identified and how the data were accessed. | Narrative description of data seeking methods provided | Main text (Methods) and methods appendix |
| 4 | Specify the inclusion and exclusion criteria. Identify all ad-hoc exclusions. | Narrative about inclusion and exclusion criteria by data type provided; Adhoc exclusions in cause specific write ups | Main text (Methods) and methods appendix |
| 5 | Provide information on all included data sources and their main characteristics. For each data source used, report reference information or contact name/institution, population represented, data collection method, year(s) of data collection, sex and age range, diagnostic criteria or measurement method, and sample size, as relevant. | An interactive, online data source tool that provides metadata for data sources by component, geography, cause, risk, or impairment has been developed | Online data citation tools |
| 6 | Identify and describe any categories of input data that have potentially important biases (e.g., based on characteristics listed in item 5). | Summary of known biases by cause included in methods appendix | Methods appendix |
| <i>For data inputs that contribute to the analysis but were not synthesized as part of the study:</i> | | | |
| 7 | Describe and give sources for any other data inputs. | Included in online data source tool | http://ghdx.healthdata.org/gbd-2016/datainput-sourcesrestricted |
| <i>For all data inputs:</i> | | | |
| 8 | Provide all data inputs in a file format from which data can be efficiently extracted (e.g., a spreadsheet as opposed to a PDF), including all relevant meta-data listed in item 5. For any data inputs that cannot be | Downloads of input data available through online | Online data visualization tools, data query tools, and the Global Health Data |

| | | | |
|-------------------------------|---|---|---|
| | shared due to ethical or legal reasons, such as third-party ownership, provide a contact name or the name of the institution that retains the right to the data. | tools, including data visualization tools and data query tools; input data not available in tools will be made available upon request | Exchange |
| Data analysis | | | |
| 9 | Provide a conceptual overview of the data analysis method. A diagram may be helpful. | Flow diagrams of the overall methodological processes, as well as cause-specific modelling processes, have been provided | Main text (Methods) and methods appendix |
| 10 | Provide a detailed description of all steps of the analysis, including mathematical formulae. This description should cover, as relevant, data cleaning, data pre-processing, data adjustments and weighting of data sources, and mathematical or statistical model(s). | Flow diagrams and Corresponding methodological writeups for each cause, as well as the demographics and causes of death databases and modelling processes, have been provided | Main text (Methods) and methods appendix |
| 11 | Describe how candidate models were evaluated and how the final model(s) were selected. | Appendix | Methods appendix |
| 12 | Provide the results of an evaluation of model performance, if done, as well as the results of any relevant sensitivity analysis. | Appendix | Methods appendix |
| 13 | Describe methods for calculating uncertainty of the estimates. State which sources of uncertainty were, and were not, accounted for in the uncertainty analysis. | Appendix | Methods appendix |
| 14 | State how analytic or statistical source code used to generate estimates can be accessed. | Appendix | Methods appendix |
| Results and Discussion | | | |
| 15 | Provide published estimates in a file format from which data can be efficiently extracted. | GBD 2016 results are available through online data visualization tools, the Global Health Data Exchange, and the online data query tool | Main text, supplementary results, and online data tools (data visualization tools, data query tools, and the Global Health Data Exchange) |
| 16 | Report a quantitative measure of the uncertainty of the estimates (e.g. uncertainty intervals). | Uncertainty intervals are provided with all results | Main text, methods appendix, and online data tools (data visualization tools, data query tools, and the Global Health Data Exchange) |
| 17 | Interpret results in light of existing evidence. If updating a previous set of estimates, describe the reasons for changes in estimates. | Discussion of methodological changes between GBD rounds | Main text (Methods and Discussion) and methods appendix |

| | | | |
|----|--|--|--|
| | | provided in the narrative of the Article and methods appendix | |
| 18 | Discuss limitations of the estimates. Include a discussion of any modelling assumptions or data limitations that affect interpretation of the estimates. | Discussion of limitations provided in the narrative of the main paper, as well as in the methodological writeups in the methods appendix | Main text (Limitations) and methods appendix |

II. Location units and time periods of the analysis

Consistent with the design of the Global Burden of Disease Study 2016, we estimated alcohol consumption and current drinker prevalence from 1990-2016 for 195 locations, which have been arranged into a set of hierarchical categories composed of seven super-regions and a further nested set of 21 regions containing 195 countries and territories, (Table 2), both sexes, and five-year age groups (age group 15-19 through age group 95+). We estimated alcohol-use attributable burden for the same 195 locations from 1990-2016, both sexes, and five-year age groups. Additionally, we calculated aggregate estimates by location and sociodemographic index (SDI). Location-level aggregates (regions, super regions, and global) are consistent with the previously published GBD location hierarchy.

Methods Appendix Table 2: Location hierarchy and SDI quintile

III. Age-standardisation

We used the GBD population standard rates as our age-standardised rates.¹

IV. Data sources

A systematic review of the literature was performed to extract data on our primary consumption indicators. The Global Health Exchange (GHDx), IHME's online database of health-related data, and Pubmed were searched for population survey data containing participant-level information from which we could formulate the required alcohol use indicators on current drinkers, lifetime abstainers, and levels of alcohol consumption.²⁻³ We documented relevant survey variables from each data source in a spreadsheet and extracted using STATA 13.1 and R 3.3.

To generate estimates of population consumption in liters per capita (LPC), we obtained data from FAOSTAT and the WHO GISAH database.⁴⁻⁵ We obtained data on the number of tourists and their duration of stay from the UNWTO.⁶ For unrecorded alcohol stock, we extracted estimates from published papers, consisting of 166 locations.⁷⁻¹² A complete list of sources can be found in the GBD data source tool: <http://ghdx.healthdata.org/gbd-2015/data-input-sources>.

We found studies used in our meta-analysis by searching Pubmed and the GHDx. The meta-analysis below lists all included studies.

For calculating attributable burden, we used estimates from GBD 2016 of deaths and DALYs for the 22 included outcomes. These estimates can be found in the GBD results tool: <http://ghdx.healthdata.org/gbd-results-tool>.

a. Inclusion criteria

We included nationally representative survey data sources that captured information on alcohol use among individuals age 15 and above. We included only self-reported drinking data and excluded data from questions asking about others' drinking behaviors. We included data that was collected between 1 January 1990 and 31 December 2016 in any of the 195 locations included in this study. For population consumption estimation, we included nationally representative sales data on alcohol availability from sources covering multiple countries. Data were included if they were collected between 1 January 1990 and 31 December 2016 and covered one of the 195 locations included in this study.

For our meta-analysis, we included all cohort and case-control studies reporting a relative risk, hazard ratio, or odds ratio for any risk-outcome pairs we included. Studies were included if they reported a categorical or continuous dose for alcohol consumption, as well as uncertainty measures for their outcomes, and the population under study was representative.

V. Consumption estimation

a. Definitions

We used four indicators to construct alcohol-use consumption, defined as follows:

1. Current drinkers, defined as the proportion of individuals who have consumed at least one alcoholic beverage (or some approximation) in a 12-month period.
2. Lifetime abstainers, defined as the proportion of individuals who have never consumed an alcoholic beverage.
3. Alcohol consumption (in grams per day), defined as grams of alcohol consumed by current drinkers, per day, over a 12-month period.
4. Alcohol liters per capita stock, defined in liters per capita of pure alcohol, over a 12-month period.

We also used three additional indicators to adjust alcohol exposure estimates to account for different types of bias:

1. Number of tourists within a location, defined as the total amount of visitors to a location within a 12 month period.
2. Tourists' duration of stay, defined as the number of days resided in a hosting country.
3. Unrecorded alcohol stock, defined as a percentage of the total alcohol stock produced outside established markets.

We used these indicators, as outlined in the modeling strategy below, to calculate a consumption estimate defined as the grams per day of pure alcohol consumed amongst drinkers.

b. Data extraction and preparation

For data in the current drinkers, lifetime abstainers, and individual-level alcohol consumption models, we extracted primary data from individual-level microdata and survey report tabulations. For microdata, we extracted relevant demographic information, including age, sex, location, and year, as well as survey metadata, including survey weights, primary sampling units, and strata. This information allowed us to tabulate individual-level data in five-year age-sex groups and produce accurate estimates of uncertainty. For survey report tabulations, we extracted data at the most granular age-sex group provided.

For data in the liters per capita mode, to provide more stable time trends in the population consumption model, we transformed FAO sales data (which calculates stock based on primary inputs) to a lagged 5-year average. Given the WHO uses FAO data in locations where the WHO could not find data using their own methods, we did not use FAO data in the locations where the WHO used FAO data to construct their estimate. To correct for bias in the underlying data generating processes between series, we adjusted the input data by running a mixed effect model on the log average of the data with dummy variables for the data series, as well as random effects on super region, region, country, and time. We adjusted the data points using the estimated parameters from the following equation:

$$\text{Log Average Data} = \beta_0 + \beta_1 D + \alpha_s + \alpha_r + \alpha_y$$

$$\text{Transformed data} = \text{data} * e^{\widehat{\beta}_1 + \widehat{\alpha}_s}$$

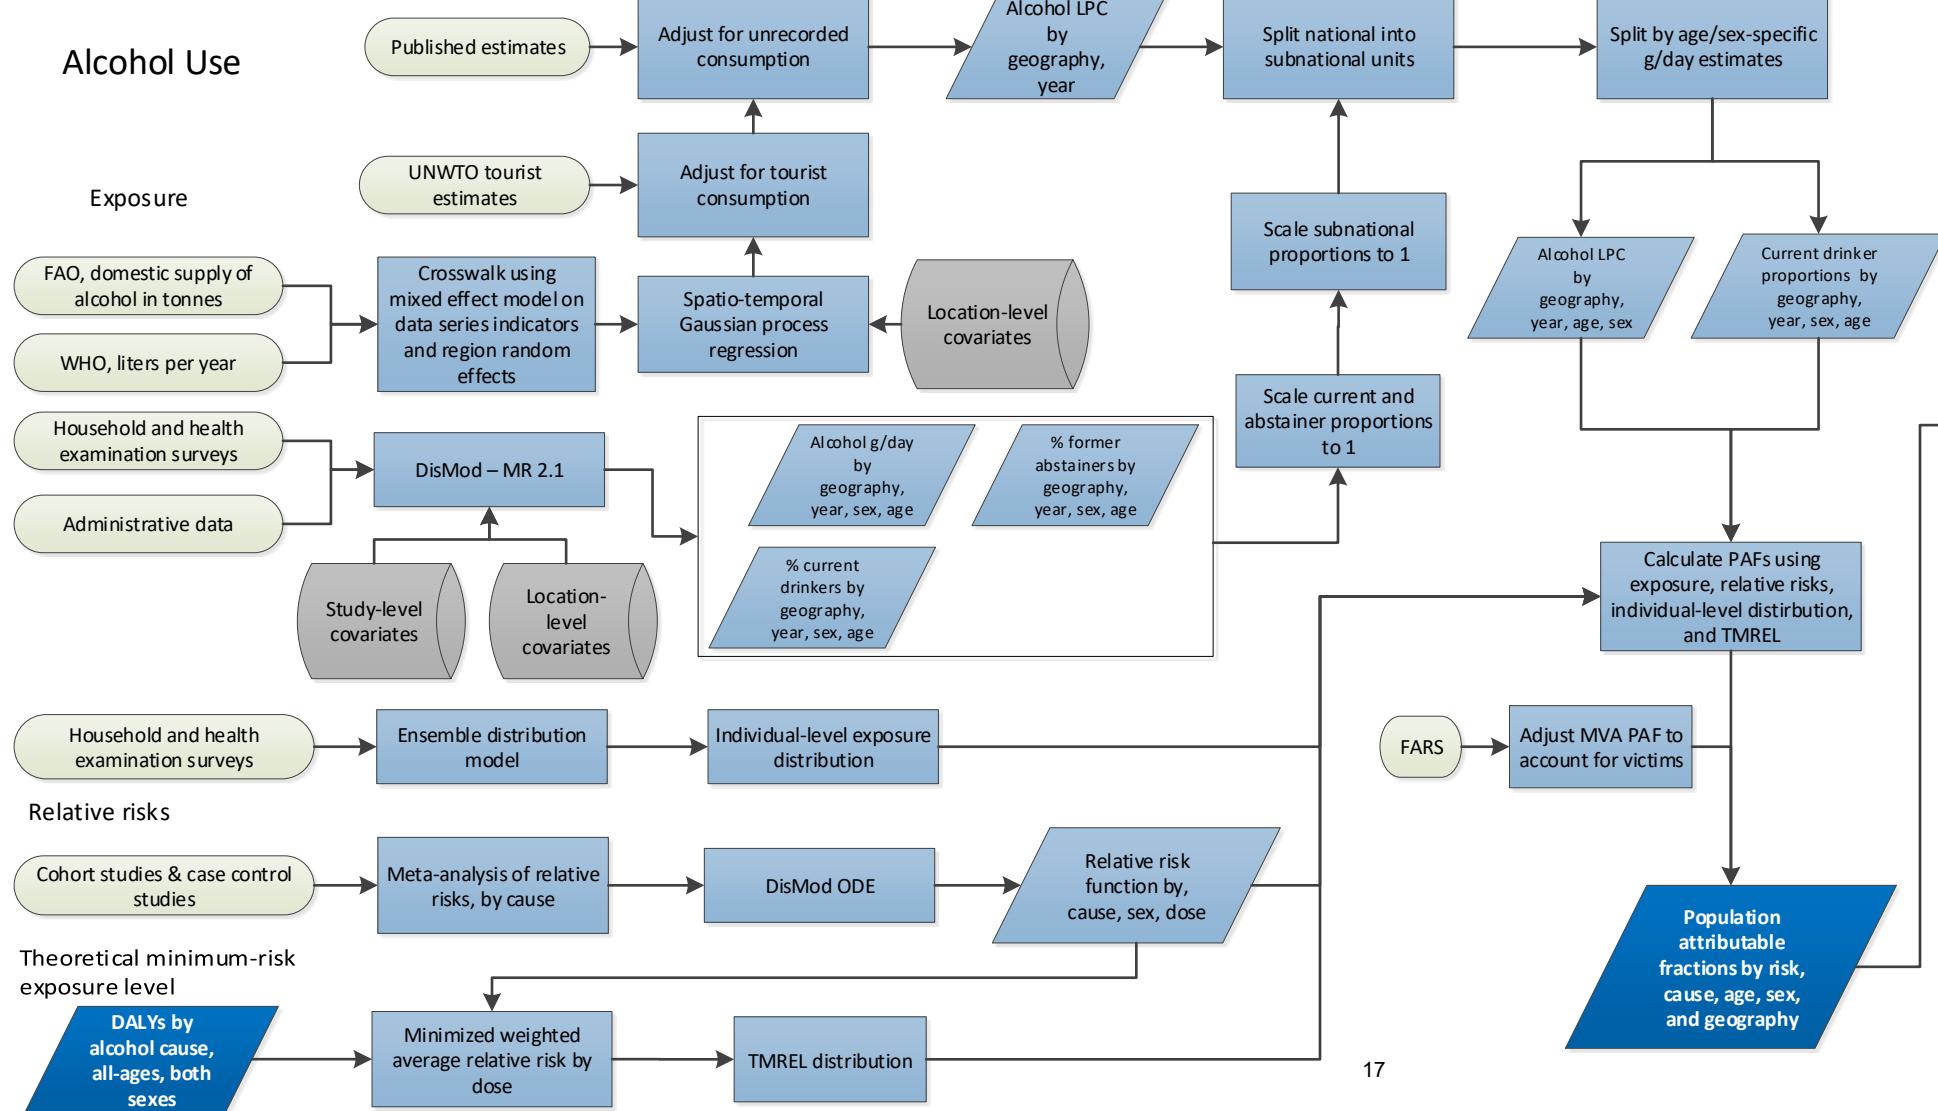

Where D is a dummy variable for a data source, α_s is a random effect for super-region, α_r is a random effect for region, and α_y is a random effect for year.

None of the data sources on liters per capita provided estimates of uncertainty, which is a component required for our eventual modeling strategy. To generate uncertainty, we ran a Loess model on the adjusted data points and the standard deviation between the difference of the Loess smoothed model and the adjusted data points across a five-year span was used as the standard deviation of the data. (i.e. If the total stock changes more variably in a narrow time frame, we believed the data to be more uncertain).

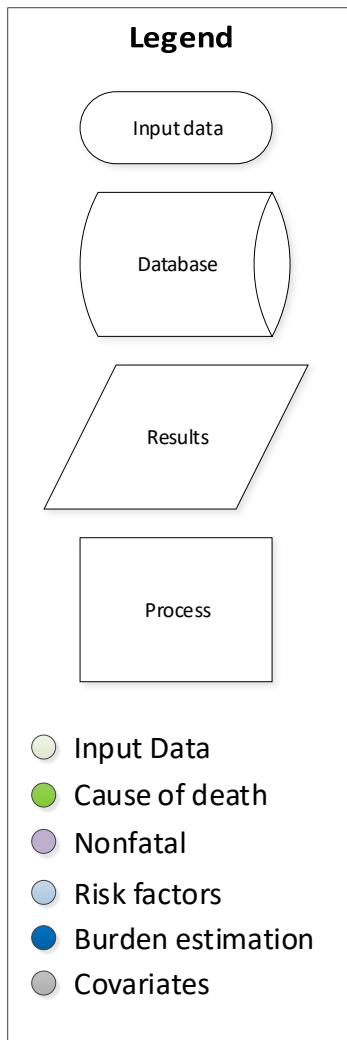

c. Modeling Strategy

In the following paragraphs and shown in the flowchart on the next page (Methods Appendix Figure 1), we outline how we estimated each primary input in the alcohol exposure model, as well as how we combined these inputs to arrive at our final estimate of grams per day of pure alcohol. We estimated all models below using 1000 draws. For all steps, R and associated packages were used.¹⁷⁻²⁰

Risk factor estimation

Methods Appendix Figure 1: Alcohol Use Flowchart

1. Population consumption in liters per capita

We modeled the alcohol liters per capita data, using a spatio-temporal Gaussian process regression (ST-GPR). The model is defined as:

$$Alcohol\ LPC = GP(m_{l,y,a,s}, cov(Alcohol\ LPC)) + \epsilon_{l,y,a,s}$$

$$m_{l,y,a,s} = \beta_0 + \beta_1(\% \text{ of population muslim})_{l,y} + \beta_2(SDI)_{l,y} + \alpha_s + \alpha_r + h(r_{l,y})$$

$$\epsilon_{l,y,a,s} = Normal(0, \sigma^2)$$

Where l is a location, y is a year period, a is an age group, and s is a sex, α_s is a random effect for super region, α_r is a random effect for region, and SDI is a location's socio-demographic index. M is the mean Gaussian process function for alcohol lpc, COV is the Matern covariance function of alcohol lpc in time and space, and $h(r_{l,y})$ is a smoothing function of the residuals in time and space, derived from hyper-parameters for time and space.

More details on the spatio-temporal Gaussian process regression and the definition of hyper-parameters within the functions above can be found in the GBD 2016 appendix (pg 18-22). ¹ Briefly, the spatio-temporal Gaussian process regression interpolates non-linear trends through time, which is particularly useful for noisy data, and does not require assumptions of a functional form for the underlying data generating process.

Hyper-parameters for the smoothing function and GPR were chosen by performing a grid search over the domains of hyper-parameter combinations. We chose the hyper-parameters and subsequent model, by minimizing the out-of-sample 10-fold cross-validated root mean squared error. Folds were chosen by holding out particular GBD regions.

2. Tourism adjustment

We adjusted the estimates for alcohol LPC for tourist consumption by adding in the per capita rate of consumption abroad and subtracting the per capita rate of tourist consumption domestically. These adjustments can be found in Methods Appendix Table 3.

$$Alcohol\ LPC_d = Unadjusted\ Alcohol\ LPC_d + Alcohol\ LPC_{Domestic\ consumption\ abroad} - \\ Alcohol\ LPC_{Tourist\ consumption\ domestically}$$

$$Alcohol\ LPC_i =$$

$$\frac{\sum_l Tourist\ Population_l * Proportion\ of\ tourists_{i,l} * Unadjusted\ Alcohol\ LPC_l * \frac{Average\ length\ of\ stay_{i,l}}{365} *}{Population_d}$$

Where l is the set of all locations, d is the domestic location, and i is either domestic consumption abroad or tourist consumption domestically.

3. Unrecorded adjustment

Given the heterogeneous nature of the estimates on unrecorded consumption, as well as the wide variation across countries and time-periods, we took 1000 draws from the uniform distribution of the lowest and highest estimates available for a given country. We did this to incorporate the diffuse uncertainty within the unrecorded estimates reported.

Methods Appendix Table 4 reports the maximum value estimated for the percentage of alcohol stock that is unrecorded. We used these 1000 draws in the above equation. We adjusted LPC only for countries where estimates were available.

We adjusted the alcohol LPC for unrecorded consumption using the following equation:

$$Alcohol\ LPC = \frac{Alcohol\ LPC}{(1 - \% Unrecorded)}$$

Methods Appendix Table 4: Maximum unrecorded estimates by location (*incorporated in the final estimates of alcohol consumption were 1000 draws from a uniform distribution between zero and the values reported here*

| Location | Maximum percentage of total alcohol stock estimated to be unrecorded |
|----------------------------------|--|
| Albania | 37% |
| Algeria | 47% |

4. Individual consumption in grams per day

We used DisMod-MR 2.1 to construct estimates for each country/year/age/sex on the prevalence of current drinking, abstention, and on individual-level consumption. We chose to use DisMod due to its ability to leverage information across the heterogeneous age groups reported in the surveys, through age-integration, as well as the model's ability to leverage information available from data in nearby locations or time-periods.

After generating complete time series for prevalence of current drinking, abstention, and individual consumption, we made sure the sum of percent current drinkers and percent abstainers summed to one for a given location/year/age/sex. We then calculated the proportion of total consumption for a given location/year by age and sex, using the estimates of individual consumption, the population size, and the percentage of current drinkers. Lastly, we multiplied this proportion of total stock for a given location/year/sex/age by the total stock for a given location/year to calculate the consumption in terms of liter per capita for a given location/year/sex/age. We then converted these estimates to be in terms of grams/per day. The following equations describe these calculations:

$$\% \text{ Current drinkers}_{l,y,s,a} = \frac{\% \text{ Current drinkers}_{l,y,s,a}}{\% \text{ Current drinkers}_{l,y,s,a} + \% \text{ Abstainers}_{l,y,s,a}}$$

$$\begin{aligned} \text{Proportion of total consumption}_{l,y,s,a} &= \\ \frac{\text{Alcohol g/day}_{l,y,s,a} * \text{Population}_{l,y,s,a} * \% \text{ Current drinkers}_{l,y,s,a}}{\sum_{s,a} \text{Alcohol g/day}_{l,y,s,a} * \text{Population}_{l,y,s,a} * \% \text{ Current drinkers}_{l,y,s,a}} \end{aligned}$$

$$\text{Alcohol LPC}_{l,y,s,a} = \frac{\text{Alcohol LPC}_{l,y} * \text{Population}_{l,y} * \text{Proportion of total consumption}_{l,y,s,a}}{\% \text{ Current drinkers}_{l,y,s,a} * \text{Population}_{l,y,s,a}}$$

$$\text{Alcohol g/day}_{l,y,s,a} = \text{Alcohol LPC}_{l,y,s,a} * \frac{1000}{365}$$

where l is a location, y a year, s is a sex, and a is a 5-year age group.

We then used the gamma distribution to estimate individual level variation within location, year, sex, age drinking populations, following the recommendations of other published alcohol studies ¹⁵. We chose parameters of the gamma distribution based on the mean and standard deviation of the 1000 draws of alcohol g/day exposure for a given population.

VI. Relative risk estimation

a. Motivation for meta-analysis

After assessing available evidence on the risk of alcohol use, we decided to conduct a new meta-analysis to improve upon existing approaches and ensure compatibility between our estimates of consumption, relative risk estimates, and aggregate measures of risk. Previous meta-analyses of alcohol use and associated outcomes have not systematically controlled for reference categories and tend to use the midpoint of consumption doses from included studies. For each included outcome, we conducted a new meta-analysis in which we have additionally collected data on the reference category within studies, as well as the width of consumption doses. This allowed us to test the significance of including within our models a confounding variable for reference category choice. It also allowed us to estimate doses continuously despite the reported heterogeneous doses of alcohol consumption, typically estimated categorically within studies.

In the following sections, we report which outcomes we included, our search strategy, the inclusion criteria, and our estimation methods. We also show, for each outcome, the PRISMA flow diagram, the data and estimates for each dose-response curve, and the references for included studies.

b. Included outcomes

Upon assessing Bradford-Hill's criteria for causation and identified studies, we calculated dose-response relative risk curves for the following outcomes: atrial fibrillation, breast cancer, cirrhosis, colo-rectal cancer, diabetes, epilepsy, esophageal cancer, hemorrhagic stroke, hypertension, ischaemic heart disease, ischaemic stroke, intentional injuries, self-harm, unintentional injuries (transport and non-transport), larynx cancer, lip & oral cancer, liver cancer, lower respiratory infection, pharynx cancer, pancreatitis, and tuberculosis.

c. Search Strategy and Inclusion criteria

For each of the above outcomes, we performed a systematic review of literature published between January 1st, 1950 and Dec 31st 2016 using Pubmed and the GHDx. Studies were included if the following conditions were met. Studies were excluded if any of the following conditions were met:

1. The study did not report on the association between alcohol use and one of the included outcomes.
2. The study design was not either a cohort, case-control, or case-crossover.
3. The study did not report a relative measure of risk (either relative risk, risk ratio, odds-ratio, or hazard ratio) and did not report cases and non-cases among those exposed and un-exposed.
4. The study did not report dose-response amounts on alcohol use.
5. The study endpoint did not meet the case definition used in GBD 2016.

For each endpoint, the search strings used, PRISMA flow diagrams, extracted data, and references can be found in the following sections.

d. Data preparation

Risk ratios (relative risk, odds-ratio, or hazard ratio) were extracted from each included study, along with the reference category used, the characteristics of the study population, and all cofounders controlled for in the study. If a study reported results in terms of standard drinkers, drinks were converted to grams per day based on the location of the study, using WHO standard drink measurements. For studies not reporting confidence intervals, we calculated uncertainty using cases, non-cases, and controls. When studies used atypical reference categories (e.g. drinkers who consume 5-10 g/day), we recalculated the relative risk using abstainers as the reference category, if possible.

e. Modeling Strategy

We used these studies to calculate a dose-response, modeled using DisMod ODE 13. We chose DisMod ODE rather than a conventional mixed effect meta-regression because of its ability to estimate nonparametric splines over doses (i.e. for most alcohol causes, there is a non-linear relationship with different doses) and incorporate heterogeneous doses through dose-integration (i.e. most studies report doses categorically in wide ranges. Our model estimates relative risks for specific doses when categories overlap across studies, through an integration step.) Model covariates for reference category choice, sex, average age, type of risk measurement, and publication year were tested. We chose the model which had the best out-of-sample coverage (using a leave-one-out strategy), given the potential covariates and spline points. When potential models had small differences in out-of-sample coverage (less than 0.1% difference), we chose the model with less covariates and spline points. We tested the possibility of estimating each curve by age and sex. If we found no significant differences in results by age or sex (e.g. the uncertainty of the first difference between models overlapped with 0), we estimated the curve for both sexes and all-ages. The majority of causes were estimated for all-ages, both-sexes, with the exception of ischemic heart disease, ischemic stroke, hemorrhagic stroke, and diabetes, which we estimated by sex.

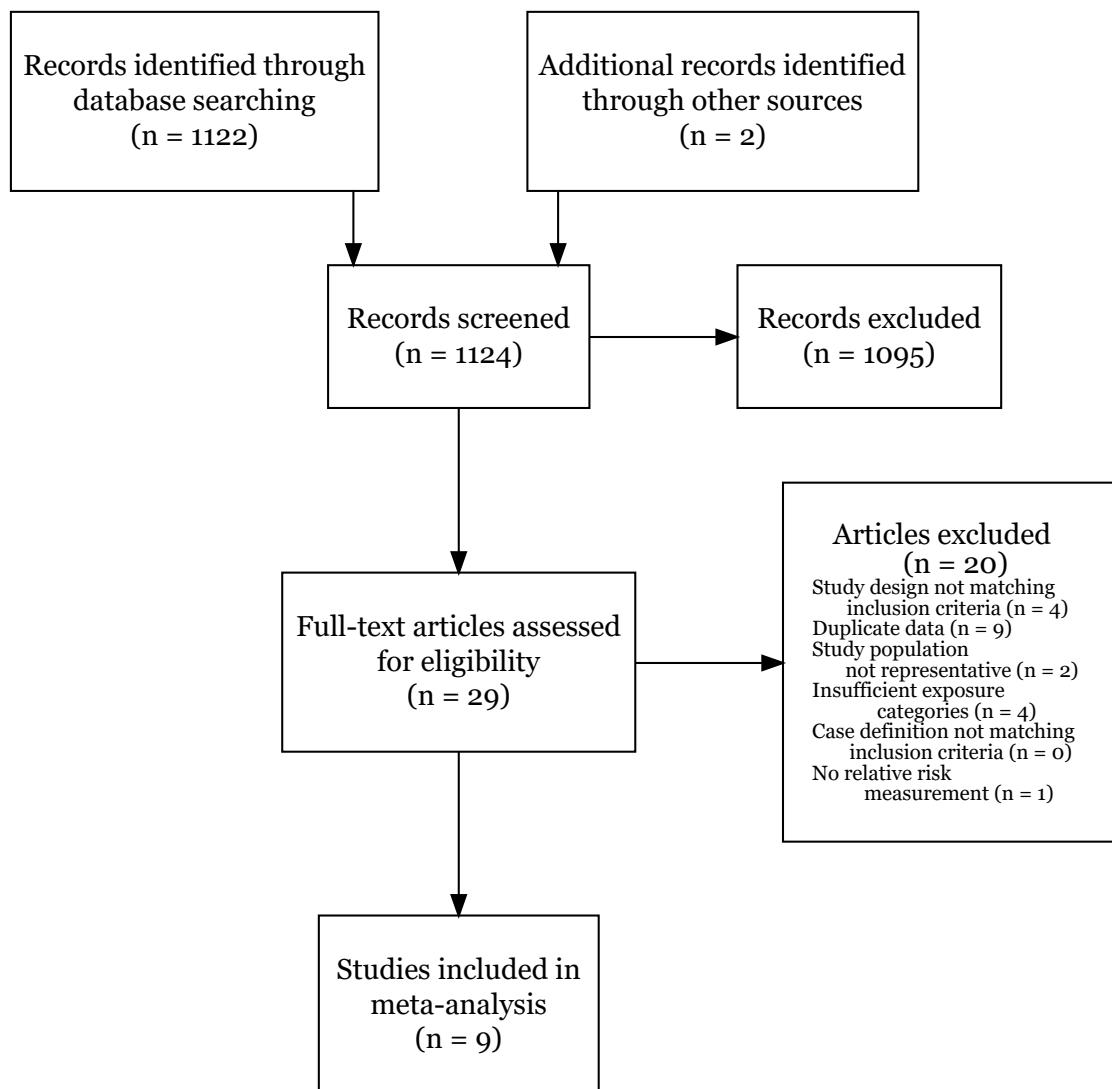

1. Atrial fibrillation and flutter

Summary of the meta-analysis conducted for GBD 2016

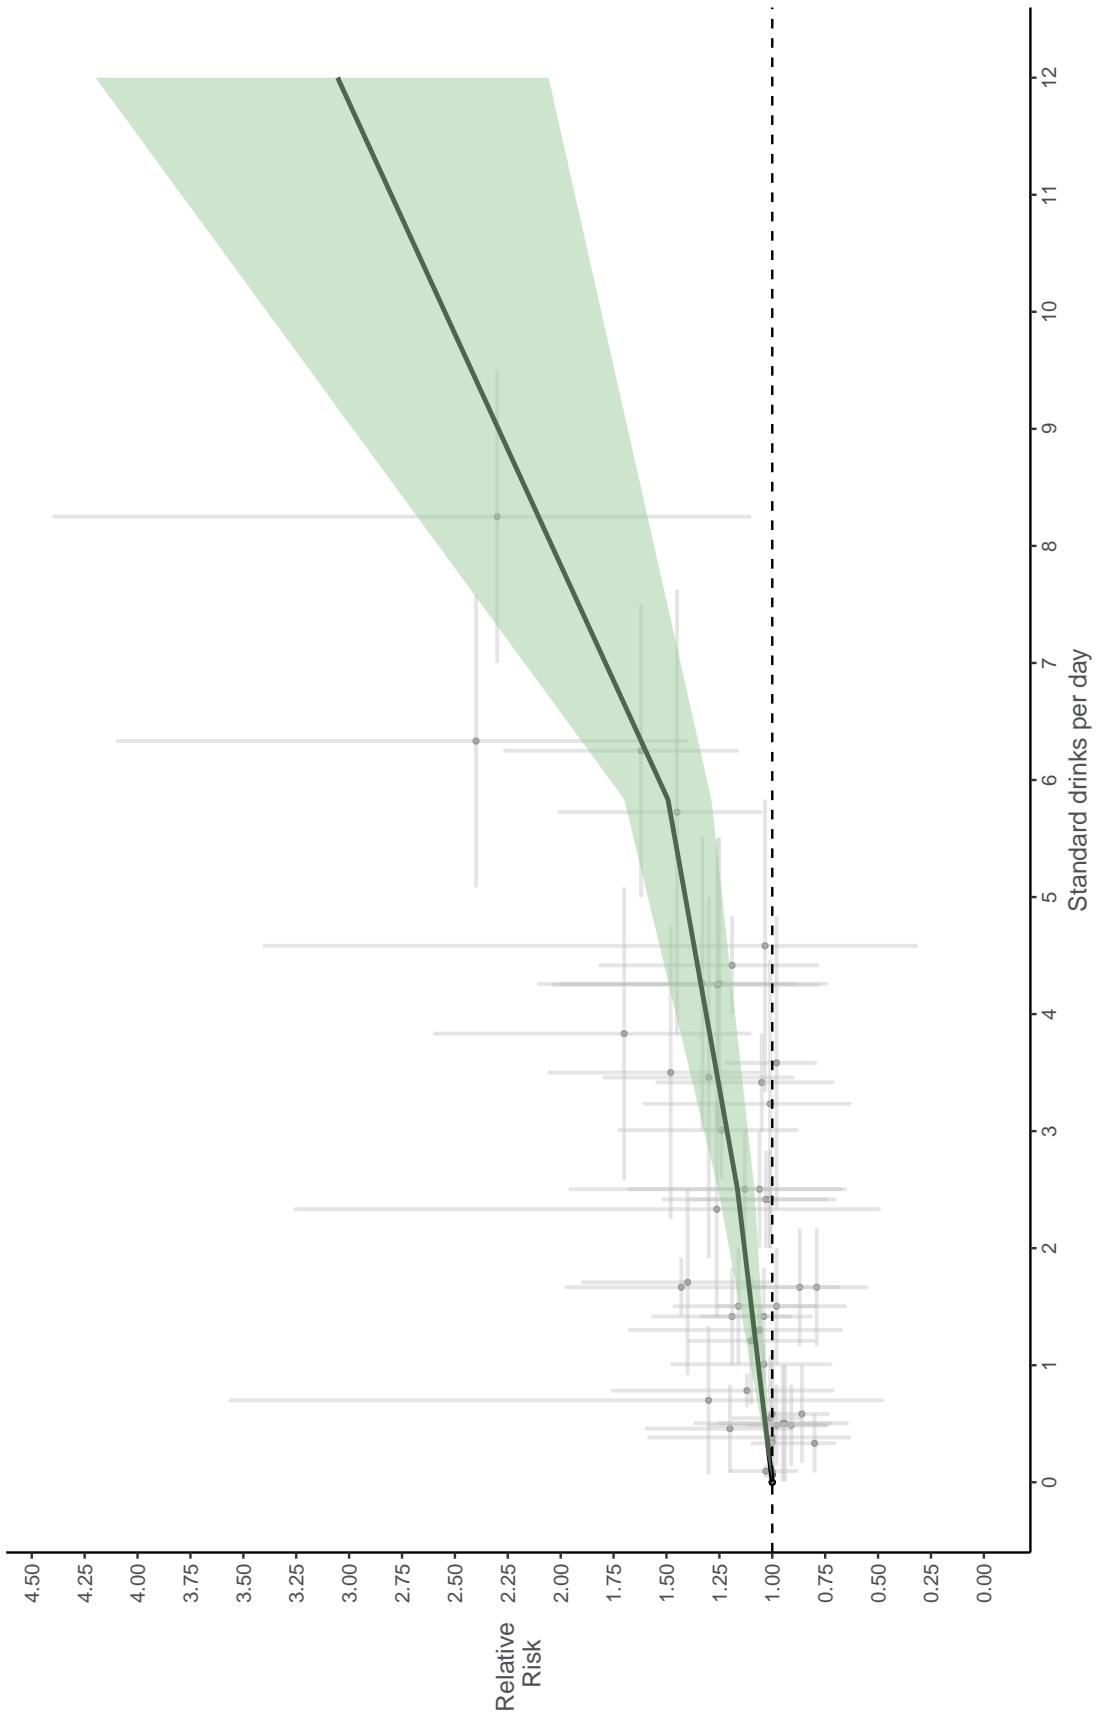

Search String:

((("ethanol"[MeSH Terms] OR "alcohols"[MeSH Terms]) AND "atrial fibrillation"[MeSH Terms]) AND ("1966/01/01"[PDAT] : "2016/12/31"[PDAT])) AND "humans"[MeSH Terms]

PRISMA flow diagram

Relative risk (RR) curves for Atrial fibrillation and flutter by number of standard drinks consumed daily. Points are relative risk estimates from studies. The vertical bars capture the uncertainty in each study, related to the sample size and the horizontal bars capture the range of drinks consumed by individuals in the study. The black line represents the estimated RR for Atrial fibrillation and flutter at each level of consumption. The shaded green areas represent the 95% uncertainty interval associated with the estimated RR. Dotted line is a reference for a relative risk of 1.

3. Cirrhosis and other chronic liver diseases

Summary of the meta-analysis conducted for GBD 2016

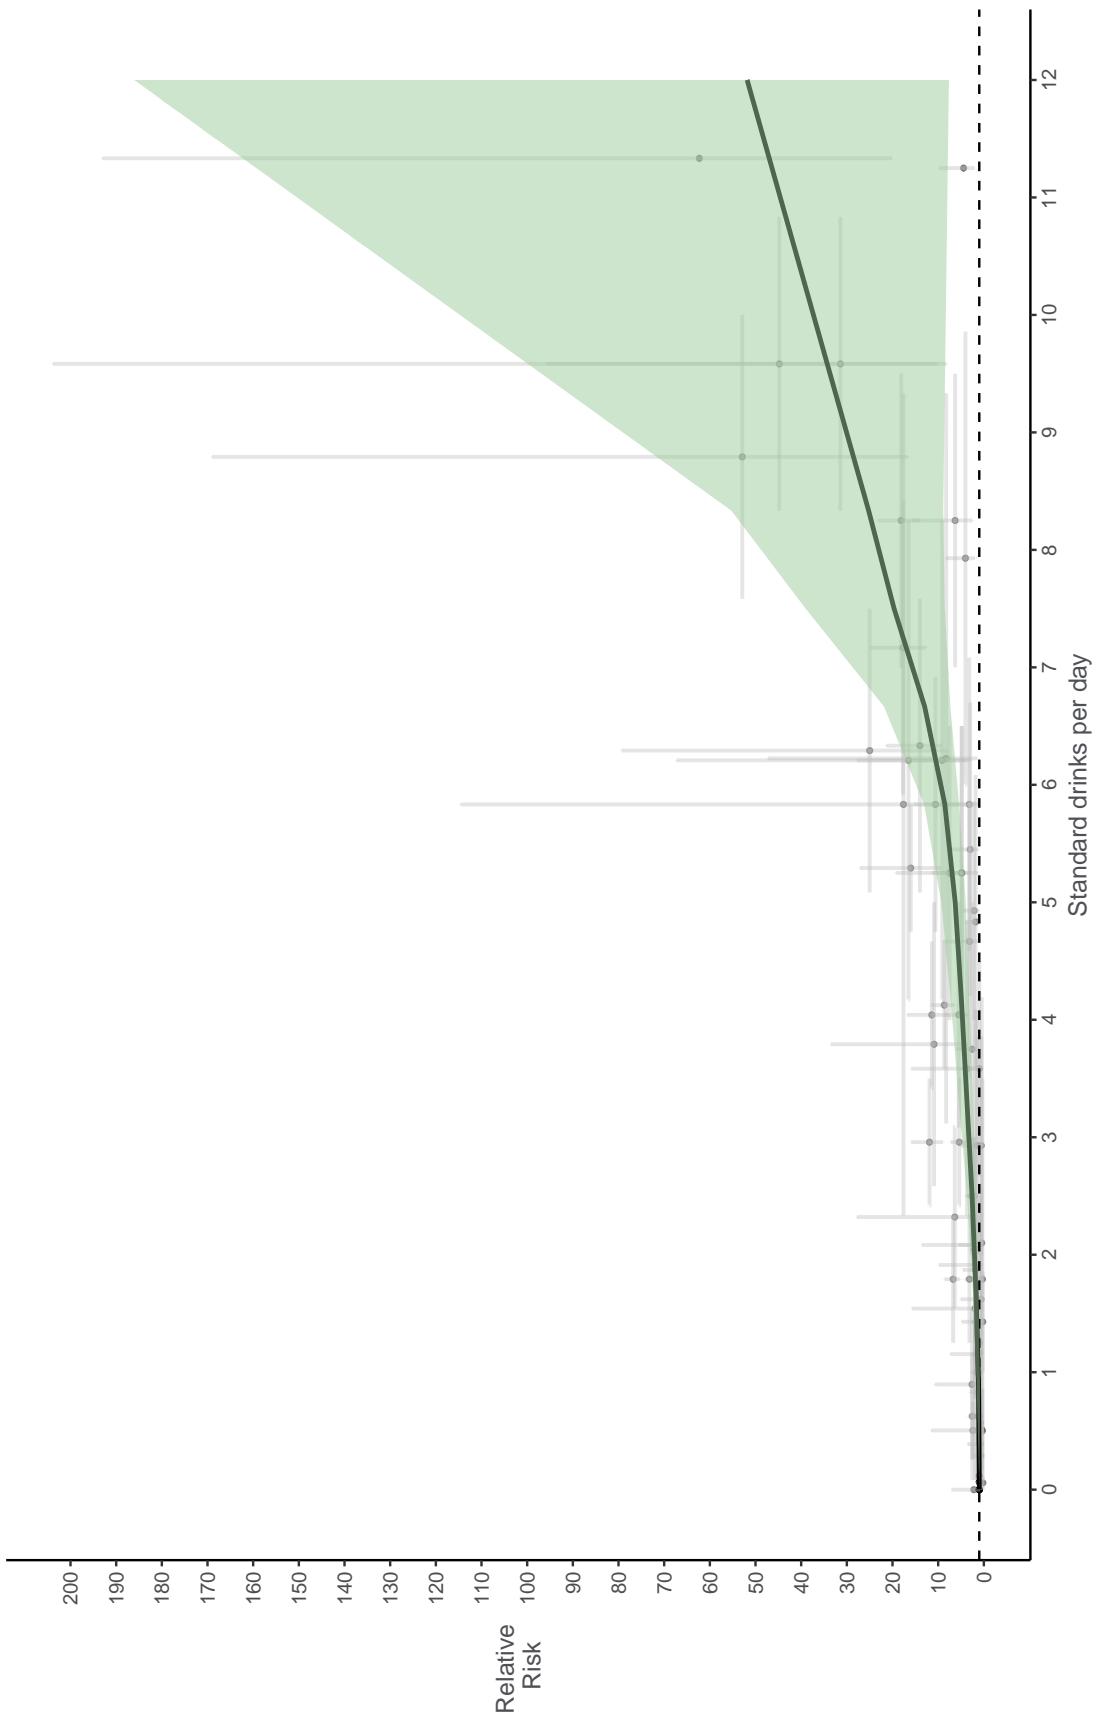

Search String:

((("ethanol"[MeSH Terms] OR "alcohols"[MeSH Terms]) AND ("liver cirrhosis"[MeSH Terms] OR "fibrosis"[MeSH Terms])) AND ("0001/01/01"[PDAT] : "2016/12/31"[PDAT])) AND "humans"[MeSH Terms]

PRISMA flow diagram

Relative risk (RR) curves for Cirrhosis and other chronic liver diseases by number of standard drinks consumed daily. Points are relative risk estimates from studies. The vertical bars capture the uncertainty in each study, related to the sample size and the horizontal bars capture the range of drinks consumed by individuals in the study. The black line represents the estimated RR for Cirrhosis and other chronic liver diseases at each level of consumption. The shaded green areas represent the 95% uncertainty interval associated with the estimated RR. Dotted line is a reference for a relative risk of 1.

Search String:

((“ethanol”)[MeSH Terms] OR “alcohols”[MeSH Terms]) AND “laryngeal neoplasms”[MeSH Terms] AND (“0001/01/01”[PDAT] : “2016/12/31”[PDAT])) AND “humans”[MeSH Terms]

PRISMA flow diagram

Relative risk (RR) curves for Larynx cancer by number of standard drinks consumed daily. Points are relative risk estimates from studies. The vertical bars capture the uncertainty in each study, related to the sample size and the range of drinks consumed. The shaded green areas represent the 95% uncertainty interval associated with the estimated RR. Dotted line is a reference for a relative risk of 1.

PRISMA flow diagram

Relative risk (RR) curves for Pharynx and nasopharynx cancer by number of standard drinks consumed daily. Points are relative risk estimates from studies. The vertical bars capture the uncertainty in each study, related to the sample size and the horizontal bars capture the range of drinks consumed by individuals in the study. The black line represents the estimated RR for Pharynx and nasopharynx cancer at each level of consumption. The shaded green areas represent the 95% uncertainty interval associated with the estimated RR. Dotted line is a reference for a relative risk of 1.

VIII. Attributable burden estimation

a. TMREL

We calculated TMREL by first calculating the overall risk attributable to alcohol. We did this by weighting each relative risk curve by the share of overall DALYs for a given cause. We then took the minimum of this all-cause risk curve as the TMREL of alcohol-use. More formally,

$$TMREL = \operatorname{argmin} \text{average overall risk}_\omega(g/\text{day})$$

$$\text{All - cause risk}_\omega(g/\text{day}) = \sum_\omega RR_i(g/\text{day}) * \frac{DALY_i}{\sum_\omega DALY_i}$$

Where ω is the set of all causes associated with alcohol, i is a given cause from that set, DALY is the global DALY rate in 2010 and RR is the dose-response curve for a given cause and exposure level in grams per day.

In other words, we chose TMREL as being the exposure that minimizes your risk of incurring burden from any given cause related to alcohol. We weight the risk for a particular cause in our aggregation by the proportion of DALYs due to that cause. (e.g. since more observed people die from IHD, we weight the risk for IHD more in the above calculation of average risk compared to, say, diabetes, even if both have the same relative risk for a given level of consumption).

b. Population Attributable Fraction calculations

For all causes, we defined PAF as:

$$PAF(x) = \frac{P_A + \int_0^{150} P(x) * RR_C(x) dx - 1}{P_A + \int_0^{150} P(x) * RR_C(x) dx} \quad P(x) = P_C * \Gamma(\mathbf{p})$$

Where P_c is the prevalence of current drinkers, P_a is the prevalence of abstainers, $RR_c(x)$ is the relative risk function for current drinkers by dose, and \mathbf{p} are parameters for the gamma distribution determined by the mean and standard deviation of exposure.

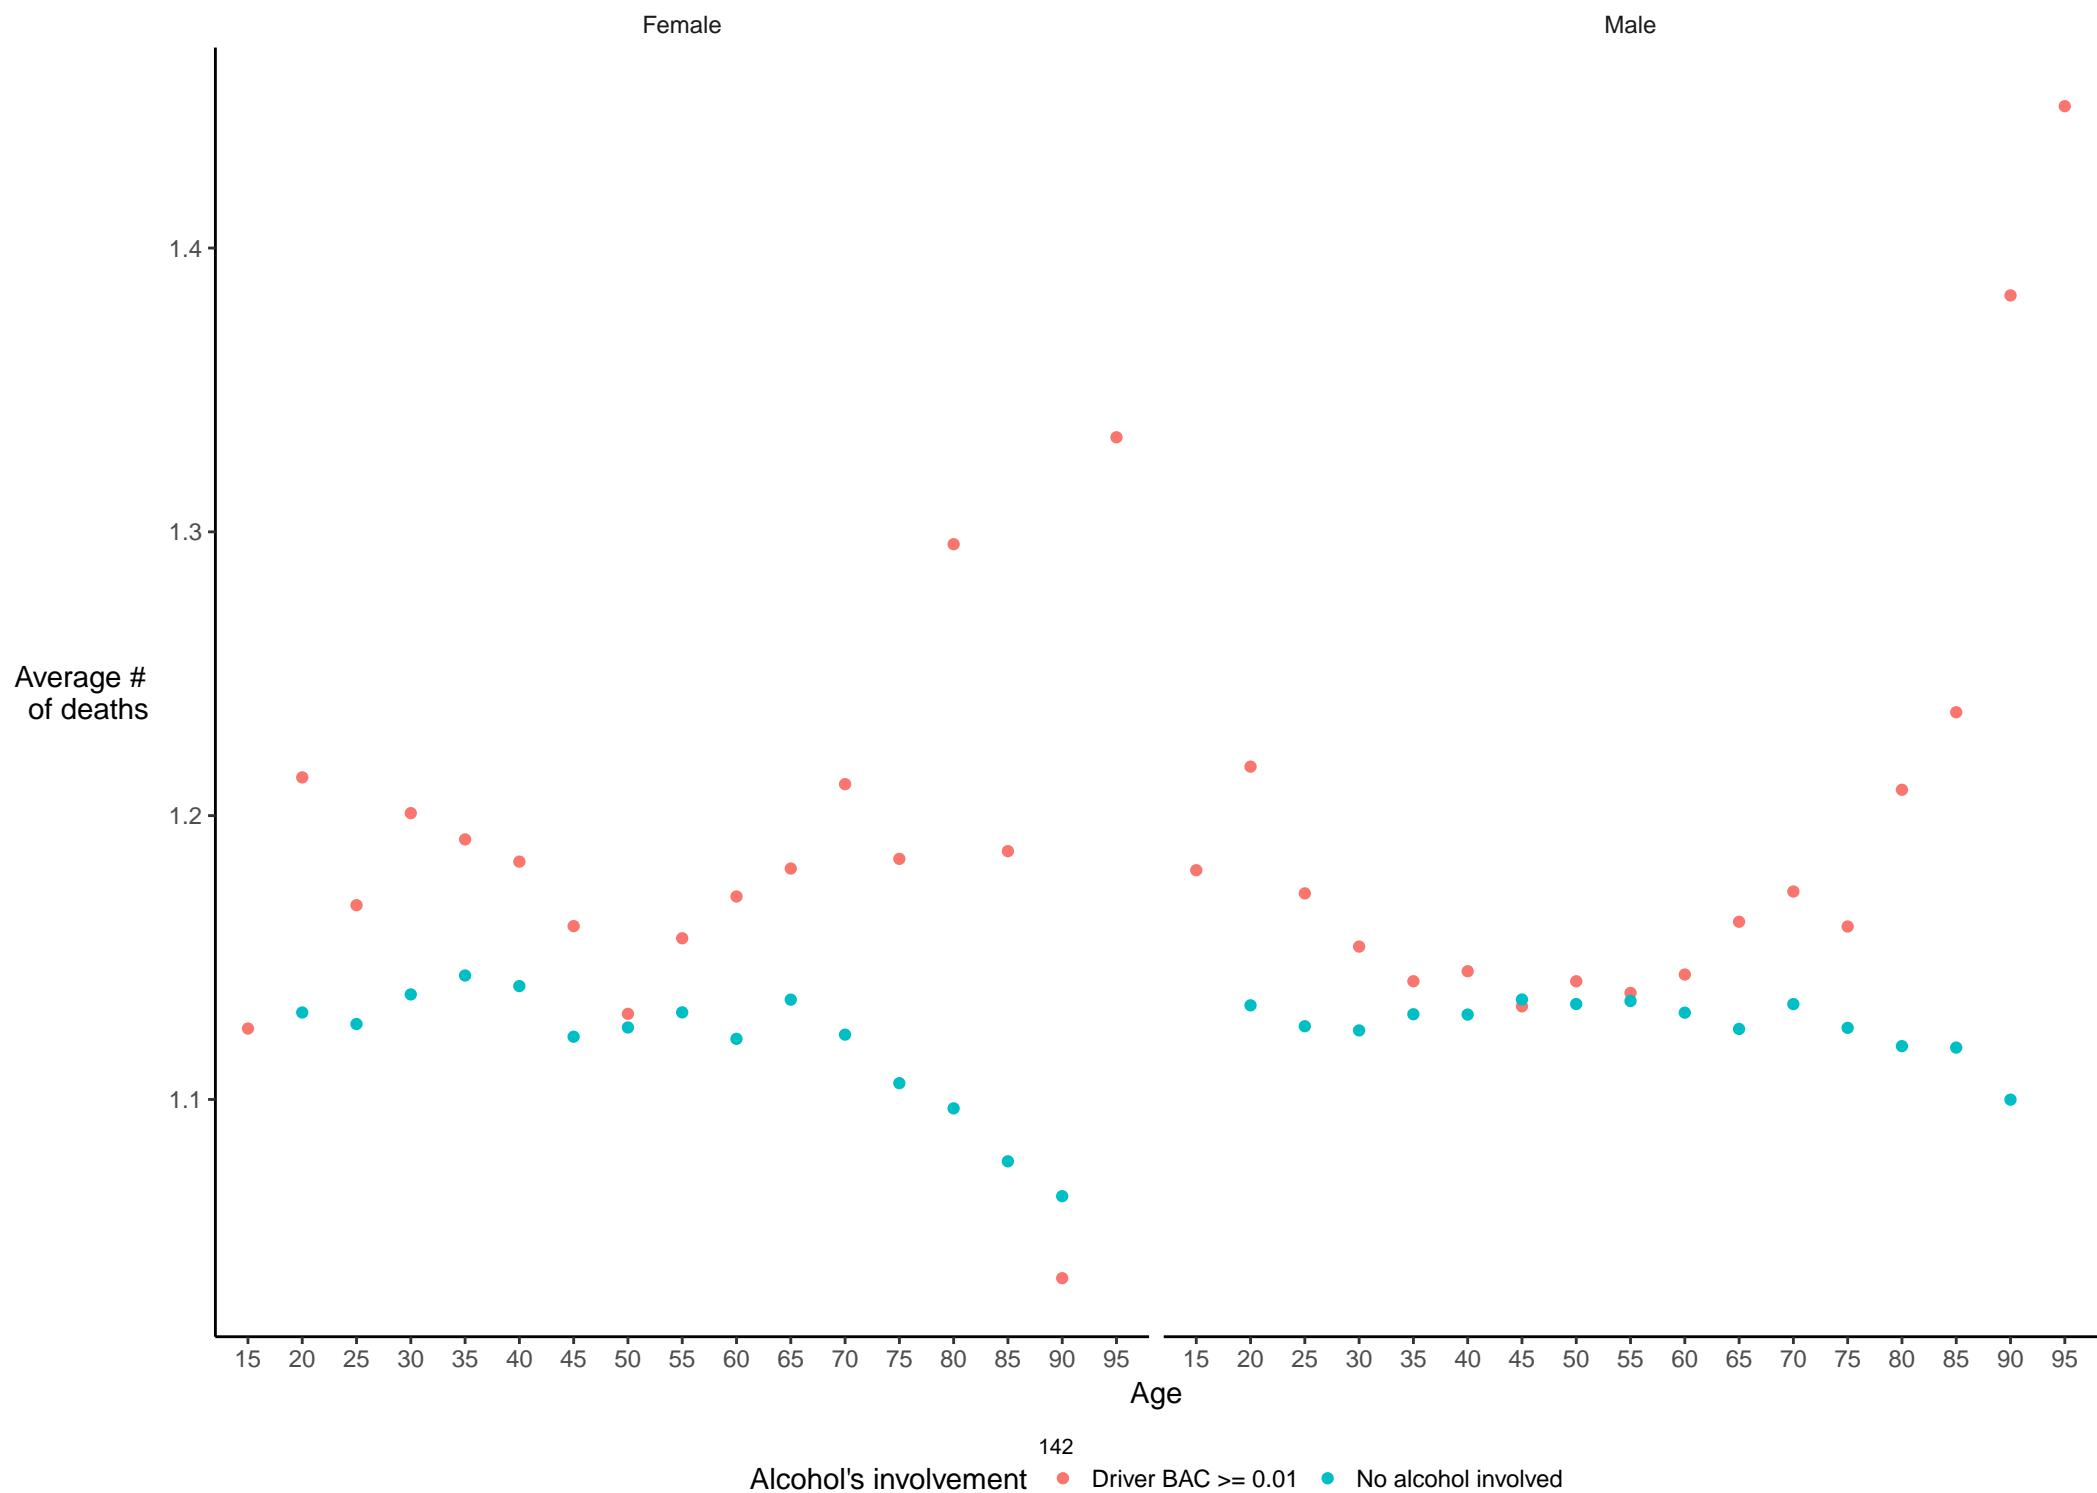

1. Motor vehicle adjustment

In the case of motor vehicle accidents, we adjusted the PAF to account for victims. Using data from the Fatality Analysis Reporting System in the US, we calculated the average number of fatalities in a car crash involving alcohol, as well as the percentage of those fatalities distributed by age and sex (shown in the pages that follow).¹⁴ We aggregated FARS data across the years 1985-2015, given there was little variation in the data temporally and the number of cases in old age groups had too much variance when constructing estimates by year. To adjust PAFs, we multiplied attributable deaths by the average number of fatalities from FARS and redistributed the PAF amongst each population, based on the probability of being a victim to a certain drunk driver by age and sex, based on the FARS data. The following equation describes this process:

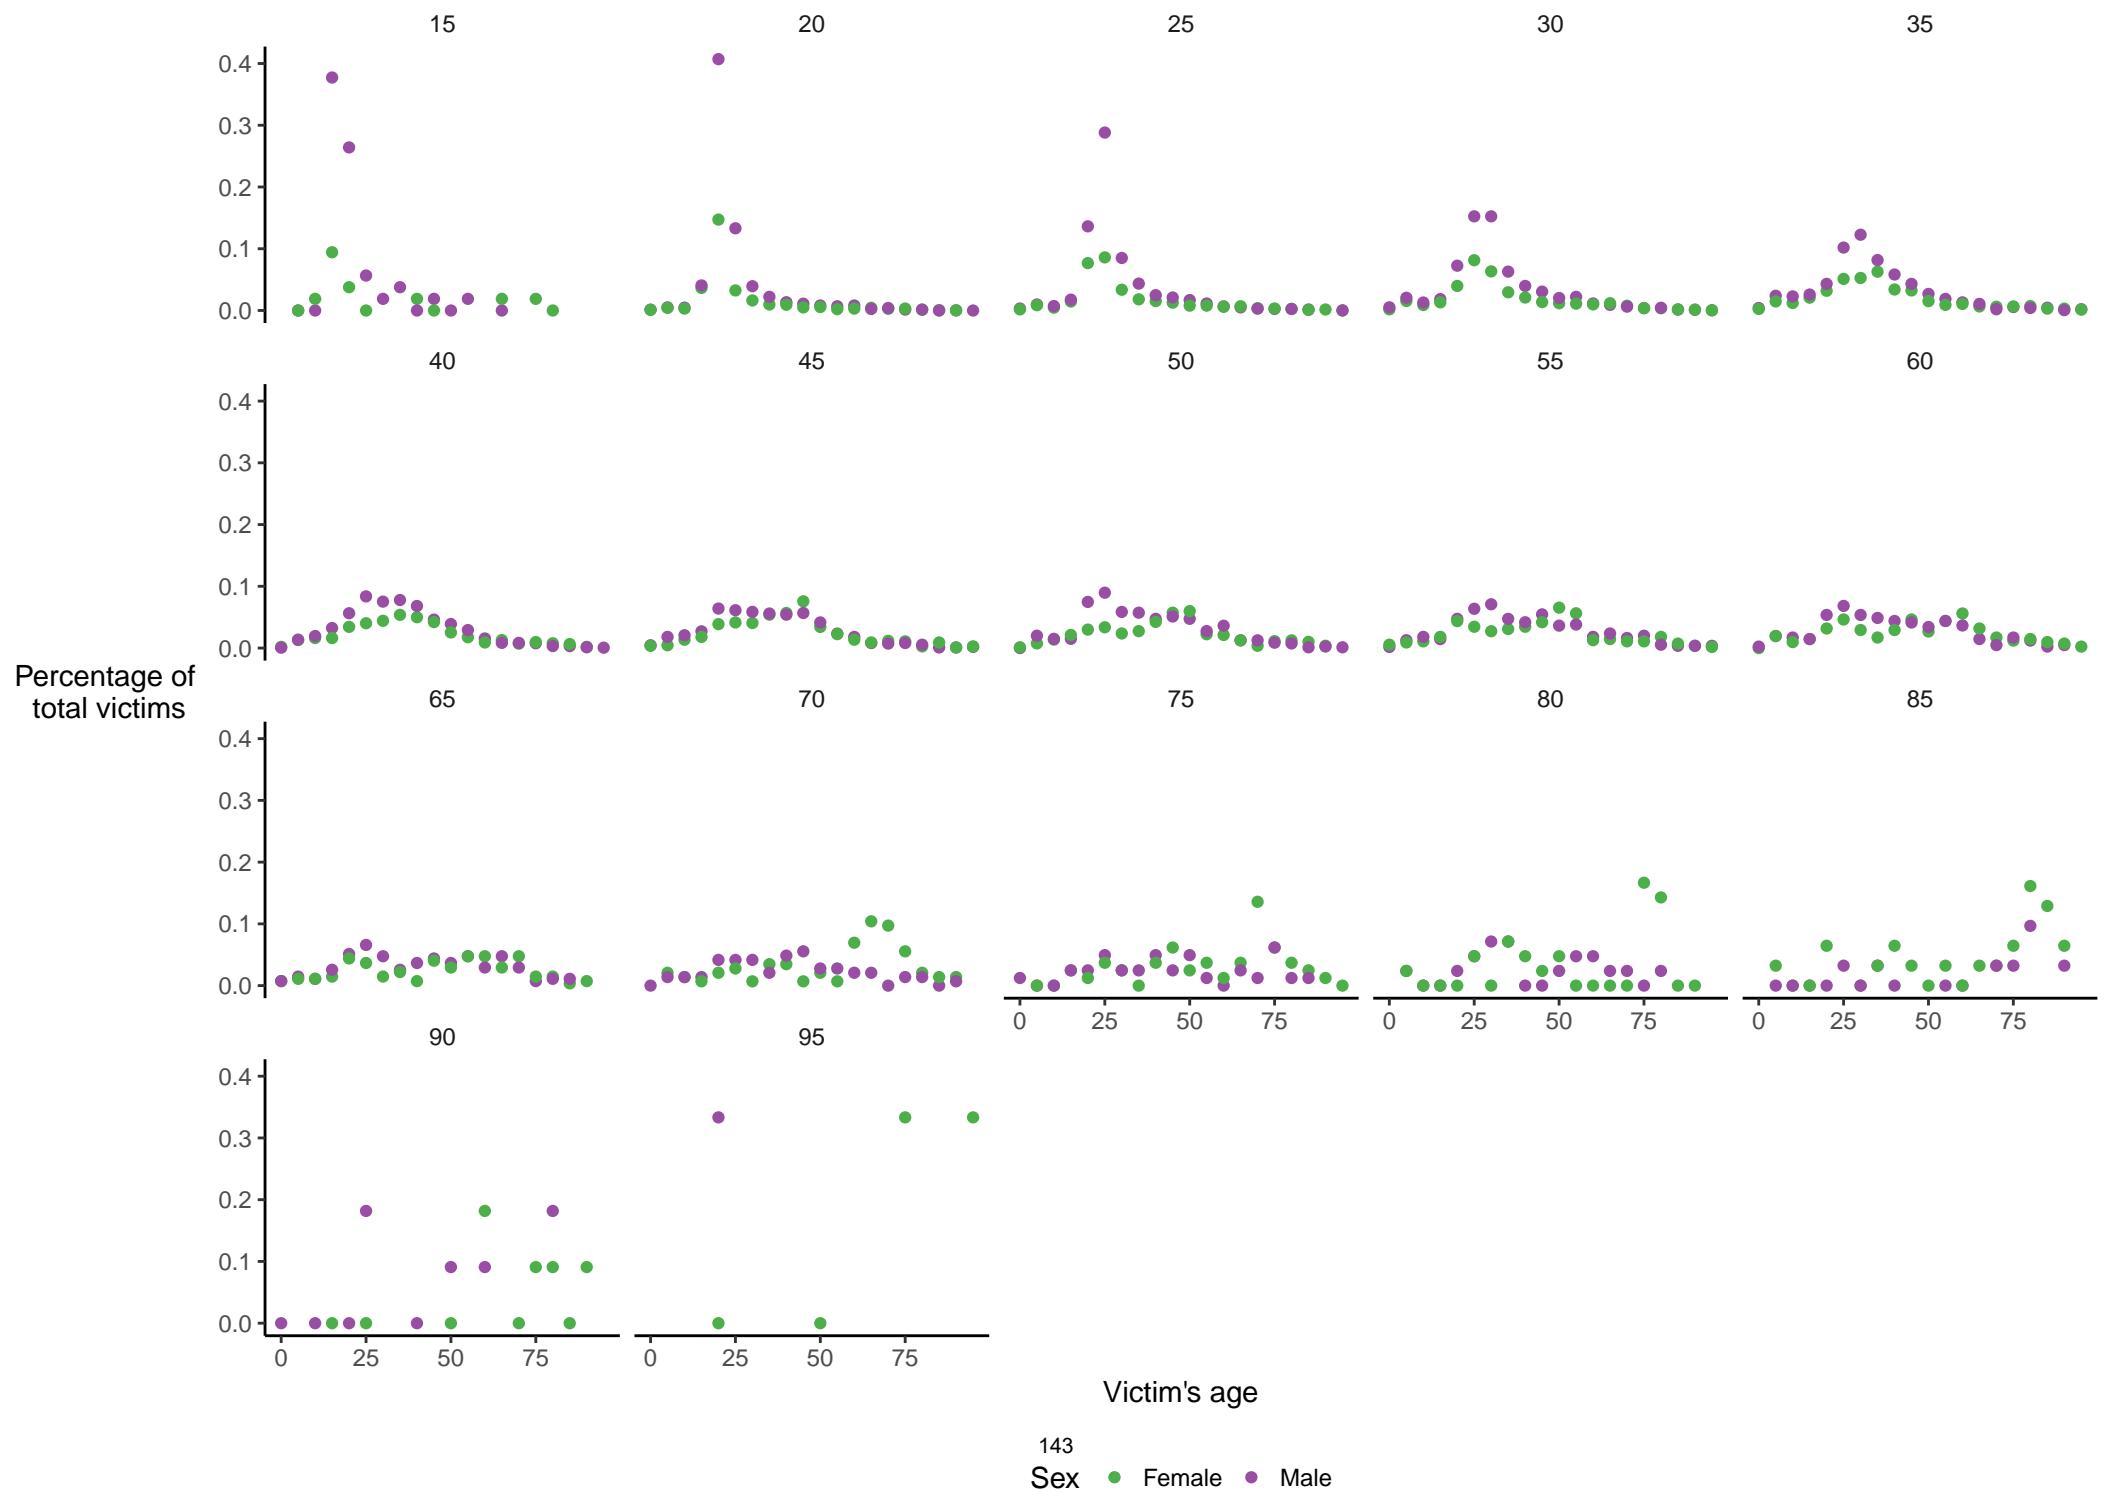

$$\text{Adjusted PAF}_i = \frac{\sum_d PAF_d * DALY_d * Avg Fatalities_d * P(i \text{ is a victim})_d}{DALY_i}$$

Where i is a population by location year, age, sex and d is the set of all age and sex groups within that location and year.

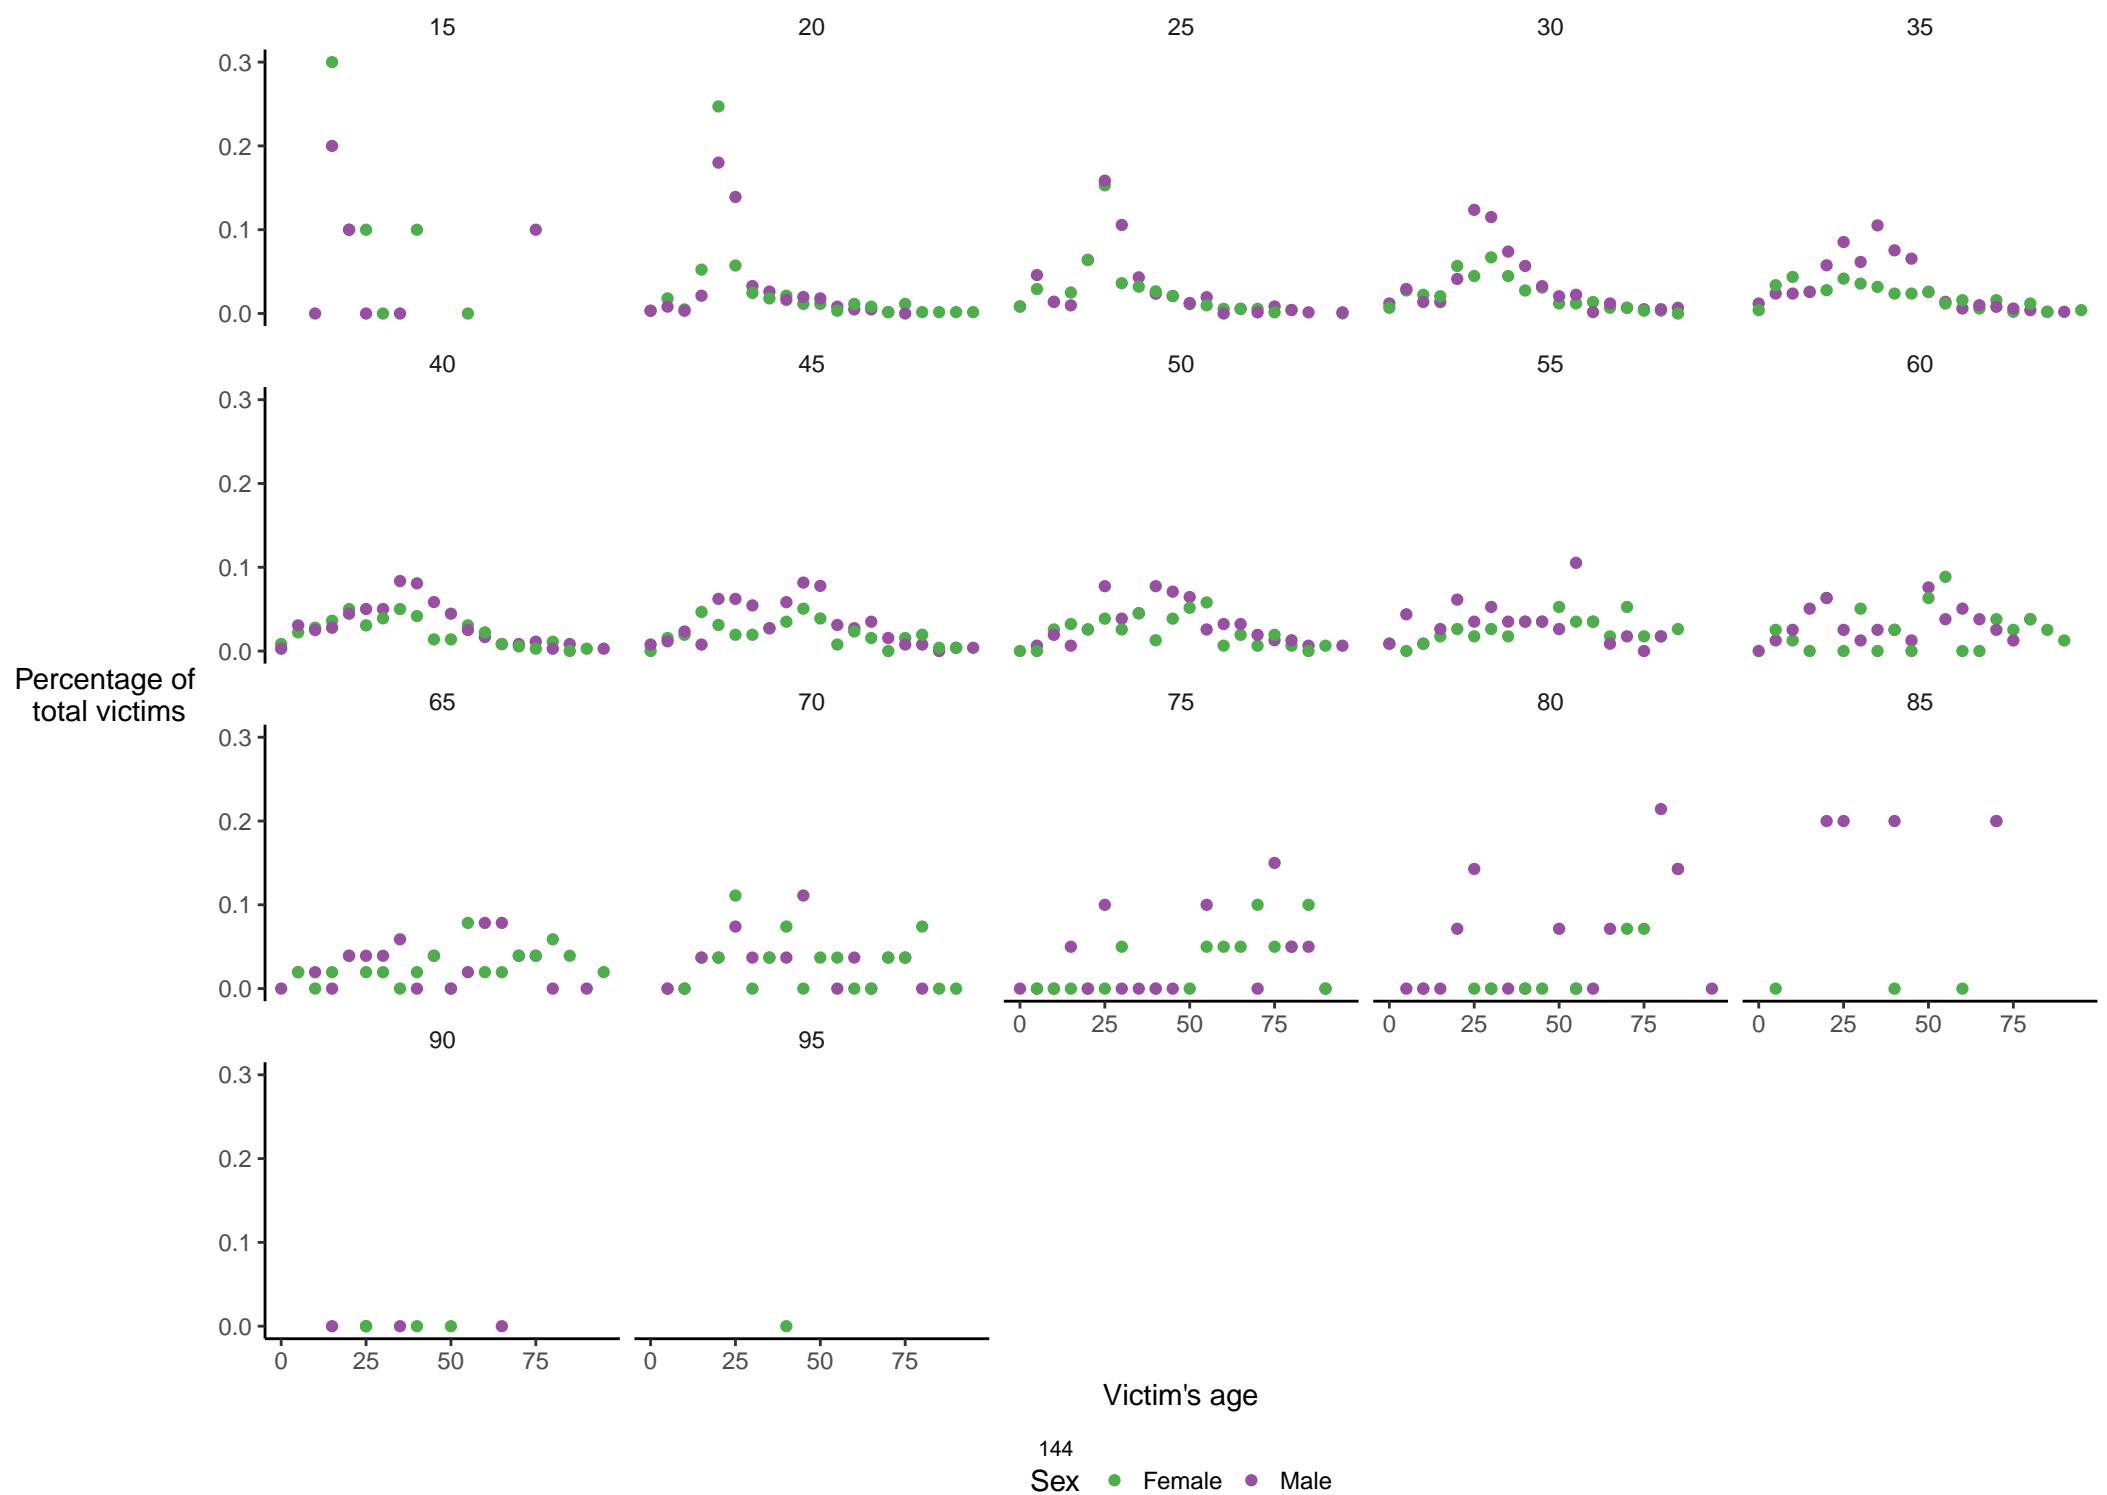

Methods Appendix Figure 2: Average number of deaths in crash
given driver's age, sex, & alcohol's involvement

Methods Appendix Figure 3: Percentage of total victims by age & sex, given the male drunk driver's age

Methods Appendix Figure 4: Percentage of total victims by age & sex, given the female drunk driver's age

c. Attributable burden calculation

We calculated 1000 draws of the exposure and relative risk models. We then used the estimated PAF draws to calculate YLL, YLDs, and DALYs, following GBD 2016 methods.¹
